## Introduction

The RSMC Tokyo - Typhoon Center (hereinafter referred to as "the Center") is the Regional Specialized Meteorological Centre (RSMC) with activity specialization in analysis, tracking and forecasting of western North Padific tropical cyclones within the framework of the World Weather Watch (WWW) Programme of the World Meteorological Organization (WMO). The Center was established at the Headquarters of the J apan Meteorological Agency (JMA) in July 1989, following the designation by the WMO Executive Council at its 40th session held in Geneva in J une 1988.

The Center conducts following operations on a routine basis:
(1) Preparation of information on the formation, movement and development of tropical cydones and associated meteorological phenomena;
(2) Preparation of information on synoptic scale atmospheric situations that affect the behavior of tropical cyclones; and
(3) Dissemination of the above information to national Meteorological Centers (NMCs), in particular to the Members of the ESCAP/WM O Typhoon Committee, in appropriate formats for operational processing.

In addition to the routine services mentioned above, the Center distributes a series of reports entitled "Annual Report on Activities of the RSMC Tokyo - Typhoon Center" to serve as operational references for the NMCs concerned. This report aims at summarizing the activities of the Center and reviewing tropical cyclones of the year.

In this 2000 issue, the outline of routine operations at the Center and its operational products are presented in Chapter 1. Chapter 2 reports the major activities of the Center in 2000. Chapter 3 describes atmospheric and oceanic conditions in the tropics and gives the highlights of the tropical cyclone activities in 2000. In Chapter 4, verification statistics of operational forecasts and predictions of the two numerical models of the Center are presented. The best track data for the tropical cyclones in 2000 are shown in table and chart forms in Appendices. All the texts, tables, charts and appendixes are included in a CD-ROM attached to this report.

The CD-ROM contains 3-hourly cloud images of all the tropical cydones in 2000 with TS intensity or higher in the area of responsibility of the Center, and software to view them. The software has various functions for analyzing satellite imagery such as animation of images, which facilitates efficient post-analysis of tropical cyclones and their environments. A setup program and a users manual for the software are also included in the CD-ROM. Appendix 7 shows an outline of the CD-ROM and how to use the software.

## Chapter 1

## Operations at the RSMC Tokyo - Typhoon Center in 2000

The area of responsibility of the Center covers the western North Pacific and the South China Sea ( $0^{\circ}-60^{\circ} \mathrm{N}, 100^{\circ} \mathrm{E}-180^{\circ}$ ) including the marginal seas and adjacent land areas (see Figure 1.1). The Center makes analyses and forecasts of tropical cyclones when they are in or expected to move into the area and provides the national Meteorological Services (NMSs) concerned with the RSMC products through the GTS, the AFTN and the J MA radio facsimile broadcast (J MH).

Figure 1.1
Area of responsibility (yellow) of the RSMC Tokyo - Typhoon Center

### 1.1 Analysis

Surface analyses are performed four times a day, at 00, 06, 12 and 18 UTC. The tropical cyclone analysis begins with the determination of the center position of a tropical cyclone. Cloud images from the Geostationary Meteorological Satellite (GMS) are the principal source for the determination of the center position, especially of tropical cyclones migrating over the data-sparse ocean area. The direction and speed of movement of a tropical cyclone are determined primarily from the six-hourly displacement of the center position.

The central pressure of a tropical cyclone is determined mainly from the Cl -number, which is derived from the satellite imagery using Dvorak's method. The CI-number also gives the maximum sustained wind speed in the vicinity of the center. Radii of circles for the galeforce wind and the storm-force wind are determined from surface observations and low-level cloud motion winds (LCW) which are derived from the cloud motion of GMS images at fifteen-minute intervals in the vicinity of the tropical cyclone.

### 1.2 Forecast

Predictions of the two numerical prediction models of J MA, Typhoon M odel (TYM) and Global Spectral Model (GSM), are the primary bases for the forecast of tropical cyclonetracks. The Persistence-Climatology method (PC method) that uses statistical techniques on the basis of linear extrapolation and climatological properties of tropical cyclone movements is al so adopted for tropical cyclones particularly in lower latitudes. The central pressure and the
maximum sustained wind speed are forecast based on the results of Dvorak's method, the PC method and the numerical prediction.

The range into which the center of a tropical cyclone is expected to move with $70 \%$ probability at each validation time is shown as the probability circle. The radius of the circle is statistically determined according to the speed of tropical cyclone movement.

### 1.3 Provision of RSMC Products

The Center prepares and disseminates the following RSMC bulletins and charts via the GTS, theAFTN or theJ MH when:

- a tropical cyclone of tropical storm (TS) intensity or higher exists in the area of responsibility of the Center;
- a tropical cyclone is expected to reach TS intensity or higher in the area within 24 hours; or
- a tropical cyclone of TS intensity or higher is expected to move into the area within 24 hours.

The RSMC products are continually issued as long as the tropical cyclone keeps TS intensity or higher within the area of responsibility. Appendix 5 denotes the code forms of the bulletins transmitted through the GTS.

RSMC Tropical Cyclone Advisory (WTPQ20-25 RJTD: via GTS)
The RSMC Tropical Cyclone Advisory reports analysis, 24-hour, 48-hour and 72-hour forecasts of a tropical cyclone for the following elements:

Analysis Center position of a tropical cyclone
Accuracy of determination of the center position
Direction and speed of movement
Central pressure
Maximum sustained wind speed (10-minute averaged)
Radii of over 50- and 30-knot wind areas

24-hour forecast
Center position and radius of the probability circle*
Direction and speed of movement
Central pressure
Maximum sustained wind speed (10-minute averaged)

48- and 72-hour forecast
Center position and radius of the probability circle*
Direction and speed of movement

* A circular range into which the tropical cyclone is expected to move with the probability of $70 \%$ at each validation time.

RSMC Guidance for Forecast (FXPQ20-25 RJTD: via GTS)

The RSMC Guidance for Forecast reports the results of numerical predictions of GSM and TYM: GSM is run twice a day with initial analyses at 00 and 12 UTC and TYM twice a day with initial analyses at 06 and 18 UTC. The Guidance presents GSM's sixhourly predictions of a tropical cyclone up to 84 hours for 00 and 12 UTC and TYM's six-hourly predictions up to 78 hours for 06 and 18 UTC. It includes:

```
NWP prediction (T=06 to 78 or 84)
                            Center position of a tropical cyclone
    Central pressure*
    Maximum sustained wind speed*
```

* Predictions of these parameters are given as deviations from those at the initial time.

## SAREP(TCNA20/21 RJTD: via GTS)

The SAREP reports a tropical cyclone analysis using GMS imagery including intensity information (CI-number) based on Dvorak's method. It is issued a half to one hour after observations at $00,03,06,09,12,15,18$ and 21 UTC and contains:

GMS imagery analysis
Center position of a tropical cyclone
Accuracy of determination of the center position
Mean diameter of the cloud system
CI-number
Apparent change in intensity in the last 24 hours
Direction and speed of movement
RSMC Prognostic Reasoning (WTPQ30-35 RJTD: via GTS)
The RSMC Prognostic Reasoning provides a brief reasoning for a tropical cyclone forecast. It is issued at 00 and 06 UTC following the issuance of the RSMC Tropical Cyclone Advisory. In the bulletin, general comments on the forecasting method, synoptic situation of the subtropical ridge, movement and intensity of tropical cyclones, and some relevant remarks are described in plain language.

RSMC Tropical Cyclone Best Track (AXPQ20 RJTD: via GTS)
The RSMC Tropical Cyclone Best Track gives post-analyzed data of tropical cyclones. It contains the center position, central pressure and maximum sustained wind. The Best Track for a tropical cyclone is distributed generally one and a half months after the termination of issuance of above RSMC bulletins for the tropical cyclone.

## Tropical Cyclone Advisory for SIGMET (FKPQ30-35 RJTD: via AFTN)

The Center, as one of the Tropical CycloneAdvisory Centres under the framework of the International Civil Aviation Organization (ICAO), provides the Tropical Cyclone Advisory for SIGMET for Meteorological Watch Offices (MWOs) concerned to support the preparation of SIGMET information on a tropical cyclone. It includes analysis, 12hour, 24 -hour forecasts of a tropical cyclone for the following elements:
Analysis and 12- and 24-hour forecasts
Center position of a tropical cyclone (analysis)
Center position of the tropical cyclone (forecast)
Direction and speed of movement
Central pressure

Maximum sustained wind speed (ten-minute averaged)

Prognostic Charts of $850-\mathrm{hPa}$ and $200-\mathrm{hPa}$ Streamline
(FUXT852/202, FUXT854/204: via JMH)
24- and 48 -hour prognostic charts of $850-\mathrm{hPa}$ and $200-\mathrm{hPa}$ streamlines as well as 850 hPa and $200-\mathrm{hPa}$ analyses are broadcast via the J MA's HF radio facsimile (J MH). These prognoses are produced with GSM at 00 and 12 UTC over the area, $20^{\circ} \mathrm{S}$ to $60^{\circ} \mathrm{N}$ in latitude and $80^{\circ} \mathrm{E}$ to $160^{\circ} \mathrm{W}$ in longitude.

### 1.4 RSMC Data Serving System

J MA has been operating the RSMC Data Serving System that allows NMCs concerned to retrieve NWP products such as Grid Point Values (GPVs) and observational data through the Internet or the Integrated Service Digital Network (ISDN) since 1995. The products and data being provided through the system are listed in Appendix 6.

## Major Activities of the RSMC Tokyo - Typhoon Center in 2000

### 2.1 Dissemination of RSMC Products

In 2000, the RSMC Tokyo - Typhoon Center provided operational products for tropical cyclone forecasting to NMCs via the GTS, the AFTN and the J MA radio facsimile broadcast (J MH). M onthly and annual total numbers of issuance of the products are listed in Table 2.1.

### 2.2 Publication

The Center published "Annual Report on Activities of the RSMC Tokyo-Typhoon Center in 1999" in November 2000 with a CD-ROM, which contains data and GMS images of all the tropical cyclones in 1999.

### 2.3 Monitoring of Observational Data Availability

The Center carried out regular monitoring of the information exchange for enhanced observations of tropical cyclones in accordance with the standard procedures stipulated in

Section 6.2, Chapter 6 of "The Typhoon Committee Operational Manual (TOM) Meteorological Component." The monitoring for this season was conducted for the following two periods:

1. from 00UTC 20 August to 18UTC 24 August (for Typhoon Bilis (0010))
2. from 00UTC 28 August to 18UTC 1 September (for Typhoon Prapiroon (0012))

The results were distributed to all the Typhoon Committee Members in February 2001, and are available on the Distributed Database of J MA at:
ftp://ddb.kishou.go.jp/pub/monitoring/rsmc.

## Chapter 3

## Atmospheric and Oceanographic Conditions in the Tropics and Tropical Cyclones in 2000

### 3.1 Summary of Atmospheric and Oceanographic Conditions in the Tropics

Sea surface temperatures (SSTs) were below normal in the central and eastern Pacific throughout the year 2000, as in 1999. In J anuary, negative SST anomalies exceeding $-1^{\circ} \mathrm{C}$ were found from the date line to $90^{\circ} \mathrm{W}$, then this negative anomaly weakened to nearly $0^{\circ} \mathrm{C}$ from spring to summer. The below-normal condition become stronger again after the mid-autumn, and SST anomalies exceeding $-1^{\circ} \mathrm{C}$ appeared around $160^{\circ} \mathrm{W}$ and $140^{\circ} \mathrm{W}$ in December. In the western part, SSTs were above normal by more than $0.5^{\circ} \mathrm{C}$ throughout the year. The SST normally for a EI Niño monitoring region $\left(4^{\circ} \mathrm{N}-4^{\circ} \mathrm{S}, 150^{\circ} \mathrm{W}-90^{\circ} \mathrm{W}\right)$ was less than $-0.5^{\circ} \mathrm{C}$ in J anuary, February, November and December. The five-month running average of the anomaly was $-0.5^{\circ} \mathrm{C}$ fromJ une 1999 to March 2000. La Niña condition continued from the summer of 1999 to the spring of 2000. Maps of monthly mean SST anomalies are held on the attached CD-ROM.

Convective activities were above normal from the Indian Ocean to Southeast Asia and Australia, while below normal over the central Pacific. This anomal ous distribution pattern typical in La Niña conditions was observed throughout this year. The inter tropical convergence zone (ITCZ) from the central to eastern Pacific was weak in the beginning of this year, and enhanced after spring and throughout summer, in the eastern and central Pacific, respectively.

The center of large-scale divergence at 200 hPa had been shifted westward from its normal position except in July and August. At 850 hPa wind field, anomalous westerly was dominant from the equatorial Indian Ocean to Indonesia, while anomalous easterly was enhanced along the western to central Pacific. At 200 hPa , wind anomalies opposite of those at 850 hPa was prevailed from the Indian Ocean to the Pacific along the equator. Associated with these wind anomalies, Walker Circulation was stronger than normal throughout 2000.

In summer the sub-tropical high sifted to the north and its extension toward the west was weak compared to the normal year. In consequence many tropical cyclones moved northward without recurving along the western periphery of the high. Figure 3.1 presents monthly mean stream line and tropical

Figure 3.1 Monthly mean stream line at 850 hPa and area of high-cloud amount greater than $30 \%$ (shaded) in J uly 2000. Tracks of the tropical cyclones (red lines) formed in J uly are superimposed.
cyclone tracks in July.
Other maps of monthly mean stream lines at 850 hPa and 200 hPa , and high-cloud amounts for the months from A pril to December are included in the attached CD-ROM.

### 3.2 Tropical Cydones in 2000

In 2000, 23 tropical cyclones of tropical storm (TS) intensity or higher were tracked in the area of responsibility of the RSMC Tokyo - Typhoon Center. The total number is smaller than the thirty-year-average of 27.8 for 1961-90. Thirteen cyclones out of them ( $57 \%$ of the total) reached typhoon (TY) intensity; the percentage is slightly larger than normal (54\%). Three out of the remainder attained severe tropical storm (STS) intensity and seven of the rest remained at TS intensity (see Table 3.1).

The tropical cyclone season of this

Figure 3.2 Genesis points of 23 tropical cyclones in 2000 (dots) and frequency distribution of the genesis points of tropical cyclones for 1951-2000 (contour), unit: number of TCs in each $4^{\circ} \times 4^{\circ}$ square. year began in early May, about one month and a half later than normal, with the development of Damrey. After the second cycloneformed near the Philippines in mid-May, tropical cyclone activity in the western North Pacific and the South China Sea was suppressed for more than one month. No tropical cyclone of TS intensity or higher was generated in J une.

In J uly cyclogenesis became active and five storms formed in total within the month. Four of them took northward tracks along the western periphery of the sub-tropical high. Among the four Kirogi, Tembin and Bolaven passed by the J apanese Archipelago. Bolaven hit the southern edge of the Korean Peninsula and Kai-tak skirted the eastern coast of the central China.

From August to September tropical cyclone activity was normal. Six and five storms were generated in August and September, respectively. Among them J elawat, Bilis and Maria made landfall on China, Kaemi and Wukong on the Indo-China Peninsula, and Prapiroon and Saomai on the Korean Peninsula during the period. These storms caused major damage to these regions. In particular Bilis, the most intense typhoon of this season, affected Taiwan seriously.

In late September cyclone activity was depressed again and no tropical cyclone of TS intensity or higher was tracked for almost one month until Yagi formed in late October. All the four tropical cyclones after Yagi became tropical storms east of the Philippines and three of them (Xangsane, Bebinca and Rumbia) made landfall on the Philippines in succession.

Other features of the tropical cyclone activity in 2000 were as follows:

- Tropical cyclones in 2000 tended to form in higher latitudes following a similar tendency in the last season. Nine storms (39\%) out of the total of 23 formed in latitudes higher than $20^{\circ} \mathrm{N}$ in contrast with $24 \%$ in the normal year (see Figure 3.2);
- Movement of tropical cyclones was slower than normal particularly in waters of higher latitudes; and
- There were many tropical cyclones which moved persistently northward through their lives without recurving.

RSMC best track data for the tropical cyclones in 2000 and maps of their tracks are shown in Appendices 1 and 3, respectively. Appendix 4 indicates the monthly and annual frequency of tropical cyclones that attained TS intensity or higher in the western North Pacific and the South China Sea for 1951- 2000.

Table 3.1 List of the tropical cyclones which attained TS intensity or higher in 2000

## Chapter 4

## Verification of Forecasts in 2000

### 4.1 Operational Forecast

Operational forecasts of the tropical cyclones of TS intensity or higher in 2000 were verified with the best track data. Verified elements are 24 -hour forecasts of the center position, central pressure and maximum sustained wind, and 48 -hour and 72 -hour forecasts of the center position. Position and intensity errors of operational forecasts for each tropical cyclone in 2000 are indicated in Appendix 2 (as Table 4.2).

### 4.1.1 Center position

Figure 4.1 shows annual mean errors of 24-hour (1982 to 2000), 48-hour (1988 to 2000) and 72-hour (1997 to 2000) forecasts of center positions. Annual mean position errors in 2000 were 153 km for 24 -hour forecast, 282 km for 48 -hour forecast and 404 km for 72 hour forecast. The 24 -hour forecast was better than 171 km of 1999, but the 72 -hour forecast was slightly worth than 389 km of 1999. The 48-hour forecast was nearly equal to that of 1999.

Figure 4.1 Annual means of position errors of 24-, 48- and 72 -hour operational track forecasts.

Position errors of 24-, 48- and 72-hour track forecasts for each tropical cyclone are summarized in Table 4.1. Among the cyclones in this season, TY J elawat, TY Bilis and TY Wukong, which took steady westward courses almost in their whole lives, scored well in the forecasts, whileTY Kai-tak, TS Maria, TS Bopha etc. were rather difficult to forecast because of their erratic movement.

Position errors were al so compared to those by the persistency (PER) method. The ratios of EO (position errors of operational forecasts) to EP (position errors of PER-method forecasts) in percentage are described in the Table 4.1. EO/EP smaller (greater) than $100 \%$ means that operational forecasts are better (worse) than PER-method forecasts. Annual mean EO/E Ps for the 24-, 48- and 72-hour forecasts in 2000 were 64\% (61\% in 1999), 50\% (52\%) and 43\% (45\%), respectively. The ratios for 2000 were similar to those for 1999, and the EO/EPs for the 48and 72-hour forecasts were the best since 1988 and 1997, respectively.

Figure 4.2 presents the histogram of 24 -, 48 - and 72 -hour forecast position errors. The ratio of 24 -hour forecast errors smaller than 150 km was $59 \%$ ( $50 \%$ in 1999), the ratio of 48 hour forecast errors smaller than 300 km was $69 \%$ (56\%) and the ratio of 72 -hour forecast errors smaller than 450 km was $70 \%$ (70\%).

Table 4.1 Mean position errors of 24-, 48- and 72- hour operational forecasts for each tropical cyclone in 2000

Figure 4.2 Position error distribution of 24-, 48- and 72-hour operational forecasts of tropical cyclones in 2000.

Table 4.3 presents mean hitting ratios and radii of $70 \%$ probability circles of operational forecasts for each tropical cyclone in 2000. The annual mean radius of $70 \%$ probability circles issued for 24 -hour position forecasts was 187 km , and their hitting ratio was $72 \%$ (in 268 out of 370 cases, a tropical cyclone actually located within the issued probability circle). As for 48 -hour forecasts, those are 327 km and $71 \%$ (in 204 out of 288 cases) respectively, and for 72 -hour forecasts, 482 km and $73 \%$ (in 154 out of 212 cases) respectively. The hitting ratios for 24 -hour and 48 -hour forecasts were $16 \%$ and $12 \%$ higher respectively, while the one for 72 hour forecasts was the same, compared to the ratio in 1999.

Table 4.3 Mean hitting ratios(\%) and radii (km) of 70\% probability circles issued for 24-, 48 - and 72 -hour operational forecasts for each tropical cyclone in 2000

### 4.1.2 Central pressure and maximum wind speed

Figure 4.3 (left) presents the histogram of central pressure errors for 24-hour forecasts. The annual mean error was $-1.2 \mathrm{hPa}(-0.8 \mathrm{hPa}$ in 1999) with a root mean square error (RMSE) of $13.0 \mathrm{hPa}(9.3 \mathrm{hPa})$. The ratio of absolute errors smaller than 7.5 hPa was $54 \%$ ( $64 \%$ ). The histogram of maximum wind speed errors for 24 -hour forecasts is also shown in the right side of the Figure. The annual mean error was $+0.8 \mathrm{~m} / \mathrm{s}(+0.3 \mathrm{~m} / \mathrm{s}$ in 1999) with a RMSE of $5.9 \mathrm{~m} / \mathrm{s}$ ( $4.6 \mathrm{~m} / \mathrm{s}$ ). $54 \%$ ( $65 \%$ ) of total forecasts had errors smaller than $3.75 \mathrm{~m} / \mathrm{s}$. The overall performance of intensity forecasts in 2000 was slightly worse than that in 1999. TY Bilis and TY Soulik, which made rapid development and weakening, were particularly difficult in their intensity forecasts.

Figure 4.3 Error distribution of 24 -hour central pressure ( hPa ) and maximum wind speed ( $\mathrm{m} / \mathrm{s}$ ) forecasts of tropical cyclones in 2000.

### 4.2 TYM and GSM Predictions

J MA's Typhoon Model (TYM) and Global Spectral Model (GSM) provide primary information for forecasters at the RSMC Tokyo - Typhoon Center to make operational track and intensity forecasts. Track predictions by TYM and GSM up to 78 and 84 hour, respectively, were verified with the best track data and predictions by the persistency (PER) method. 24hour, 48-hour and 72 -hour intensity predictions by TYM and GSM were also verified with these data. The PER-method assumes that a tropical cyclone holds its intensity and movement throughout the forecast period based upon the linear extrapolation of the latest 6hour track of a tropical cyclone. Prediction errors by the PER-method are used to evaluate the relative performance of model predictions.

### 4.2.1 TYM prediction

## 1) Center position

Annual mean position errors of TYM predictions since 1996 are indi cated in Figure 4.4. In 2000, a total of 224 predictions were made by TYM and errors for 30-hour*, 54hour* and 78-hour* predictions in 2000 were $173 \mathrm{~km}, 313 \mathrm{~km}$ and 502 km , respectively. The performance of TYM track prediction in 2000 was almost the same as in 1999 for the forecast period for 30 -hours, but worse from 42-hours to 78 -hours compared to the

Figure 4.4 TYM annual mean position errors since 1996. previous year. Mean position errors of 18-, 30-, 42-, 54-, 66 - and 78 -hour predictions for each tropical cyclone are also shown in Table 4.4.

Note: 30-, 54- and 78-hour predictions by TYM and GSM are the primary information for forecasters in preparing 24-, 48- and 72 -hour operational forecasts, respectively.

Table 4.5 gives TYM's relative performance compared to the PER-method. In this comparison, life stages of tropical cyclones were classified into three categories, "Before", "During" and "After" recurvature. Each stage is defined with the direction of movement of each tropical cyclone at each prediction time concerned. The Table indicates that TYM outperformed the PER-method throughout the whole forecast period beyond 18 hours from the initial time and improvement rates were roughly $30 \%$ for 18 -hour, $40 \%$ for 30 -hour, $45 \%$ for 42 -hour and $50 \%$ for 54 -hour to 78 -hour predictions. Looking at the results of respective stages, improvement rates were relatively higher in "During" and "After" stages in which position errors were larger compared with "Before" stage.

Figure 4.5 (in the attached CD-ROM) presents histograms of the position errors of 30-, 54 - and 78 -hour predictions of TYM. The ratio of 24 -hour prediction errors smaller than 150 km was $47 \%$ ( $46 \%$ in 1999), the ratio of 54 -hour prediction errors smaller than 300 km was $61 \%$ (67\%) and the ratio of 78 -hour prediction errors smaller than 450 km was $57 \%$ (58\%).

Table 4.5 Mean position errors (km) of TYM and PER predictions for the tropical cyclones in 2000 in each stage of motion. Number of samples is given in parentheses

## 2) Central pressure and maximum wind speed

TYM has a certain plus bias in the central pressure prediction and that for 30-hour predictions in 2000 was +5.2 hPa with a root mean square error (RMSE) of 15.6 hPa . Meanwhile the bias for 30 -hour maximum wind speed predictions was $-1.4 \mathrm{~m} / \mathrm{s}$ with a RMSE of $7.1 \mathrm{~m} / \mathrm{s}$. Figure 4.6 shows histograms of the errors of 30 -hour central pressure and maximum wind speed predictions. About $52 \%$ of the central pressure predictions had errors with absolute values less than 7.5 hPa , while $44 \%$ of the maximum wind speed predictions with absolute values less than $3.75 \mathrm{~m} / \mathrm{s}$.

Figure 4.6 Error distribution of TYM 30-hour intensity predictions of tropical cyclones

### 4.2.2 GSM Prediction

## 1) Center position

GSM annual mean position errors since 1996 indicated in Figure 4.7 show that the overall performance of GSM track predictions in 2000 was the best in the years. The errors for 30 -hour, 54hour and 78 -hour predictions were 165 $\mathrm{km}, 276 \mathrm{~km}$ and 402 km , respectively. Although prediction cases of GSM and TYM were not homogeneous, the errors of GSM were smaller than TYM particularly in later hours of forecast period. The improvement of the

Figure 4.7 GSM annual mean position errors since 1996. performance of GSM in 2000 owes to the recent version-up of GSM made in December 1999. The version-up included the incorporation of cloud water content as a prognostic variable, a modification of the prognostic ArakawaSchubert cumulus parameterization, and the calculation of direct effect of aerosols on shortwave radiation.

A total of 239 predictions was made by GSM in 2000 and mean position errors of the 18-, 30-, 42-, 54-, 66- and 78-hour predictions for each tropical cydone are given in Table 4.6.

Table 4.7 gives GSM 's relative performance compared to the PER-method. I mprovement rates were roughly $35 \%$ for 18 -hour, $45 \%$ for 30 -hour, $55 \%$ for 42 -hour, $55 \%$ to $60 \%$ for 54 -, 66 and 78 -hour predictions. The percentage is relatively high in "during" and "After" stage. The rates were about $5 \%$ to $10 \%$ higher than TYM in almost whole stages at each prediction time.

Table 4.7
Mean position errors (km) of GSM and PER predictions for the tropical cyclones in 2000 in each stage of motion

Figure 4.8 (in the attached CD-ROM) presents histograms of the position errors of 30-, 54 - and 78 -hour predictions of GSM. The ratio of 30 -hour prediction errors smaller than 150 km was $58 \%$ ( $43 \%$ in 1999), the ratio of 54 -hour prediction errors smaller than 300 km was $70 \%$ (58\%) and the ratio of 78 -hour prediction errors smaller than 450 km was $72 \%$ ( $70 \%$ ). The overall performance of track forecasts in 2000 was better than that in 1999 as already described in the first paragraph of this section.

## 2) Central pressure and maximum wind speed

Figure 4.9 shows histograms of central pressure errors and the maximum wind speed errors of 30 -hour predictions of GSM. About $45 \%$ of the predictions had absolute errors less than 7.5 hPa , while predictions with errors smaller than $3.75 \mathrm{~m} / \mathrm{s}$ account for $30 \%$ of the total. The performance of intensity predictions in 2000 was considerably improved due to the version-up of GSM in December 1999. However, the histograms show that GSM still underestimates the intensity of tropical cyclones in its 30-hour predictions.

## TY DAMREY (0001)

A tropical depression formed east-northeast of Palau Islands at 18UTC 4 May 2000. Moving northwestward, the depression attained TS intensity at OOUTC 7 May and was named Damrey, the first one from the new name list that became effective 1 J anuary 2000 for tropical cyclones in the western North Pacific and the South China Sea. It then began to move northeastward east of the Philippines and developed into a typhoon on the following day. Accelerating gradually, Damrey reached peak intensity with maximum sustained winds of 90 knots at 06UTC 9 May. It further continued to move northeastward for a couple of days with gradual weakening and crossed around Ogasawara-shoto (islands) south of J apan around 12UTC 11 May. Turning to the east, it downgraded to a tropical storm at 06UTC on the following day and became an extra-tropical cyclone at 12UTC of the day.

## TS LONGWANG (0002)

Longwang formed as a tropical depression in the South China Sea near the western coast of Luzon at 06UTC 17 May. It moved northeastward and became a tropical storm south of J apan at OOUTC 19 May. On the northeastward track, Longwang kept TS intensity until 06UTC 20 May, when it transformed into an extra-tropical cyclone south of Japan. The cyclone continued to move northeastward for further several days and crossed the International Date Line.

## TY KIROGI (0003)

After one-month rest of tropical cyclone activity in J une, a tropical depression formed east of the Philippines at 06UTC 2 J uly. Moving northward, it attained TS intensity at 06UTC 3 J uly and devel oped rapidly into a typhoon southwest of Okinotorishima at 18UTC of the day. Kirogi then changed its movement to the north-northeast and reached its peak with maximum sustained winds of 85 knots west of the island at OOUTC 5 J uly. On the northnortheastward track, it passed between small islands, south of J apan on the midnight of 8 J uly and approached the eastern coast of J apan. During the passage, a wind gust of $49.3 \mathrm{~m} / \mathrm{s}$ was observed at Hachijo-jima (47678). Weakening to STS intensity, it moved al ong the eastern coast of J apan and turned to the east around 18UTC 9 July. Shortly after the turn it transformed into an extra-tropical cydone.

Kai-tak was the first typhoon developed in the South China Sea in this season. It formed as a tropical depression west of Luzon at 12UTC 3 July and initially took a northward track. It then slowed down northwest of Luzon and quickly developed to a tropical storm at 18UTC 5 J uly, to a typhoon at 12UTC 6 J uly. Kai-tak reached peak intensity at 00UTC 7 J uly and maximum sustained winds of 75 knots were estimated. Right after reaching its peak, it began to move northeastward and made landfall on the eastern part of Taiwan around OOUTC 9 J uly. During the passage it turned to the north with weakening and crossed the eastern tips of central China on the morning of 10 J une. Later Kai-tak transformed into an extra-tropical cyclone in the northern part of the Yellow Sea at 18UTC 10 July.

TS TEMBIN (0005)

A tropical depression formed at 00UTC 17 J uly north of the Mariana Islands. Moving northwestward initially, then northward the depression became a tropical storm around Ogasawara-shoto at OOUTC 19 J uly. Keeping TS intensity, Tembin continued to move northward until it was downgraded into a tropical depression about 200 km southeast of J apan at 18 UTC 21 J uly.

## STS BOLAVEN (0006)

Bolaven formed as a tropical depression east of Luzon at OOUTC 24 J uly and moved north-northeastward. Turning to the east-northeast, it attained TS intensity around Okinawa at 18UTC 25 J uly. After passing south of Okinawa on the morning of 26 J une, the storm made an anti-dockwise turn keeping TS intensity over waters east of Okinawa from 26 to 28 J uly. Decreasing its translation velocity, it developed into a severe tropical storm at 06UTC 29 J uly. As Bolaven moved northward further southwest of J apan, it weakened to a tropical depression at the southern tip of the Korean Peninsula at OOUTC 31 J uly, and transformed into an extra-tropical cycl one shortly.

## TS CHANCHU (0007)

Chanchu was a short-lived system, which formed as a tropical depression east of the Marshall Islands at 18UTC 27 J uly. The depression moved to the north-northwest and became a tropical storm east of the Islands at 18UTC 28 J uly. After moving northward with TS intensity for one day, it weakened to a tropical depression east of Wake Island at 18UTC 29July.

## TY JELAWAT (0008)

A tropical depression formed south of Marcus Island at 18UTC $31 \mathrm{~J} u l y$. Moving westward, the depression developed rapidly and became a tropical storm at 12UTC 1 August and a typhoon at 00UTC of the following day. On the west-northwestward track J elawat reached peak intensity with maximum sustained winds of 85 knots north of the Mariana Islands at OOUTC 3 August. It kept TY intensity for several days moving westward and passed near Minamidaito-jima (47945) around 06UTC 6 August. J erawat then turned to the northwest and passed near Okinawa on the early morning of 8 August. A wind gust of $61.5 \mathrm{~m} / \mathrm{s}$ was observed at Minamidaito-jima during the passage. As J ELAWAT entered the E ast China Sea, it weakened gradually and was downgraded to a severe tropical storm near the central coast of China at 06UTC 10 August. Shortly from the downgrade it made landfall on the coast and further weakened to a tropical depression at 18UTC of the day.

## TY EWINIAR (0009)

A tropical depression formed west of Guam Island at 00UTC 9 August. It moved westward initially, then northward and became a tropical storm over the same waters at 18UTC of the day. Accelerating to the north, the storm attained STS intensity southwest of Ogasawara-shoto at O6UTC 11 August. E winiar slowed down south of J apan and began moving to the east-northeast around 12UTC 12 August. The storm continued to move east-northeastward over the next three days keeping STS intensity until 18UTC 15 August when it intensified into a typhoon east of J apan. Maximum sustained winds of 65 knots were estimated at the time. As it turned to the north, it lost tropical characteristics gradually and became an extra-tropical cyclone at 12UTC 18 August.

## TY BILIS (0010)

Bilis was the most intense tropical cyclone of this season, which was generated as a tropical depression northwest of Yap Island at 12UTC 18August. It took a northwestward track in its almost whole life until making landfall on southern China. Developing gradually on the northwestward track east of the Philippines, Bilis attained TS intensity at 06UTC 19 August, TY intensity at 12UTC 20 August and reached its peak with maximum sustained winds of 110 knots northeast of Luzon at 18UTC 21 August. With TY intensity Bilis made landfall on Taiwan around midnight of 23 August. After the landfall it weakened rapidly and landed on the southeast coast of China before the noon of the day. As it moved to inland of China, it further weakened to a tropical storm at 06UTC 23 August and to a tropical depression shortly.

## TS KAEMI (0011)

K aemi was a very short-lived system, formed as a tropical depression in the South China Sea at 12UTC 19 August. Moving westward initially, then northwestward the depression reached TS intensity about 200 km east of Viet Nam at 12UTC 21 August. On the northwestward track, Kaemi made landfall on the central coast of Viet Nam around 06UTC 22 August. After the landfall, it weakened to a tropical depression at 12UTC 22 August.

## TY PRAPIROON (0012)

A tropical depression, which formed northwest of Yap Island at 18UTC 24 August, moved westward initially and turned to the north. It became a tropical storm west of Okinotorishima at 18UTC 26 August turning to the northwest. After Prapiroon attained STS intensity at 18UTC 27 August on the northwestward track, it drifted to the west until 12UTC 28 August when it began to move northward. On the accelerating northward track, the storm passed around Okinawa on the evening of 29 August. A wind gust of 36.6 $\mathrm{m} / \mathrm{s}$ was observed at Miyako-jima (47927). In the E ast China Sea the cyclone developed to a typhoon at 06UTC 30 August, reached peak intensity at 12UTC of the day and maximum sustained winds of 70 knots were estimated. After crossing the Yellow Sea, Prapiroon hit the northern part of the K orean Peninsula with STS intensity on the night of 31 August. It then weakened gradually and transformed into an extra-tropical cyclone at 12UTC 1 September.

## TS MARIA (0013)

A tropical depression formed southeast of Hong K ong at 06UTC 27 August. It took a southward track and became a tropical storm at 12UTC of the following day. Keeping TS intensity, Maria continued to move southward in the northern South China Sea for about two days. It then stopped southward movement about 500 km west of Luzon and remained almost stationary until OOUTC 30 August, when it began to make a clockwise turn. After the turn Maria moved northward and made landfall on the southern coast of China on the early morning of 1 September. Shortly after the landfall it weakened to a tropical depression.

## TY SAOMAI (0014)

SAOMAI was a long-lived tropical cyclone, which maintained TS intensity or higher almost two weeks. A tropical depression formed far east of the Mariana Islands at 18UTC 31 August and moved northward initially, then turned to the west. On the westward track, it developed into a tropical storm at 12UTC 2 September and a typhoon east of Saipan Island at 06UTC 4 September. It turned to the south and weakened into STS grade at 06UTC 5 September. At 06UTC 6 September it changed the track to the west and then to the northwest. On its steady northwestward track through the following several days, it kept STS intensity until OOUTC 9 September, when it re-developed to attain TY intensity. Saomai further devel oped and reached peak intensity with maximum sustained winds of 95 knots southeast of Minamidaito-jima at 12UTC 10 September. It then passed the central portion of Okinawa Island just after 10UTC 12 September. A wind gust of $42.0 \mathrm{~m} / \mathrm{s}$ was observed during the passage. In the East China Sea it changed the track northeastward, and then north-northeastward increasing its translation velocity. After weakening into STS intensity, Saomai made landfall on the southern coast of the Korean Peninsula around 2OUTC 15 September. Moving north-northeastward, SAOMAI transformed into an extratropical cyclone at 06UTC 16 September northeast off the K orean Peninsula.

## TS BOPHA (0015)

A tropical depression, which formed east of Luzon at 06UTC 4 September, moved east initially, then made a gradual anti-clockwise turn to the west-northwest on 6 September. It intensified into a tropical storm southeast of Minamidaito-jima at 18UTC 6 September. After passing just south of Okinawa Island on 08 September, Bopha made another anti-clockwise turn to the south on 9 September. Keeping TS intensity, it passed east off Taiwan from the night of 9 to the morning of 10 September and made landfall on Luzon around 23UTC 10 September. The storm weakened into a tropical depression on the northern coast of Luzon at 00UTC 11 September.

## TY WUKONG (0016)

Wukong formed as a tropical depression west of Luzon at 06UTC 4 September. It remained almost stationary until 12UTC 5 September and then made an anti-clockwise turn to the west in the South China Sea. During the turn the depression developed into a tropical storm at OOUTC 6 September. It further intensified to attain TY intensity at 18UTC 7 September and reached its peak with maximum sustained winds of 75 knots at 06UTC 8 September. Weakening gradually, Wukong skirted around the southern coasts of Hainan Island on 9 September and made landfall on the northern part of Vietnam around 04UTC 10 September. After the landfall it weakened into a tropical depression in the northeastern part of Thailand at 12UTC of the day.

## STS SONAMU (0017)

A tropical depression, which formed southwest of Iwo-jima at 06UTC 14 September, moved northward and developed into a tropical storm south of the island at 03UTC 15 September. It turned to the north and passed just west of Ogasawara-shoto around 12UTC 16 September. A half day later Sonamu attained STS intensity southeast of J apan and then made a slight turn to the north-northeast on 17 September. The storm transformed into an extratropical cyclone near the Chishima Islands at 06UTC 18 September

## TY SHANSHAN (0018)

A tropical depression formed northeast of the Marshall Islands at 06UTC 17 September. M oving northwest, it devel oped into a tropical storm at 12UTC 18 September and one day later attained TY intensity over the same waters. Shanshan further intensified passing northeast of Wake Island and reached its peak with maximum sustained winds of 95 knots north of the island at 12UTC 21 September. Turning to the northeast, Shanshan accelerated its translation velocity with gradual weakening on 22 and 23 September. The storm transformed into an extra-tropical cyclone northwest of Midway Island at 18UTC 24 September.

## TY YAGI (0019)

Almost one month later after Shanshan dissipated in late September, YAGI formed as a tropical depression north of the Mariana Islands at OOUTC 21 October. Moving west-northwest, it developed into a tropical storm east-northeast of Okino-torishima at OOUTC 22 October. The storm kept moving west-northwestward with gradual development and attained TY intensity south of Okinawa at 12UTC 24 October. After YAGI reached its peak with maximum sustained winds of 70 knots, it changed the track to the northwest, then turned to the north and made a full turn over the waters around Okinawa from 26 to 28 October. YAGI weakened gradually during the turn and downgraded into a tropical depression over the same waters at 00UTC 27 October.

## TY XANGSANE (0020)

A tropical depression formed southeast of Yap Island at 18UTC 24 October 2000. It gradually developed moving west-northwestward and became a tropical storm east of the Philippines at 06UTC 26 October. On the west-northwestward track, the storm attained STS intensity at OOUTC 27 October and made landfall on the east coast of the Philippines around 21UTC 27 October. It slightly weakened passing Luzon and entered the South China Sea on the early morning of 29 October. Xangsane then decelerated westward movement and almost remained stationary until 18UTC 29 October, when it started moving to the north-northeast. Shortly the storm re-intensified to attain TY intensity at OOUTC 30 October and reached its peak with maximum sustained winds of 75 knots west of Luzon. Xangsane continued to move north-northeastward for the following two days keeping TY intensity and passed just east of Taiwan on the morning of 1 November. Entering the East China Sea, it turned to the northeast and transformed into an extratropical cyclone at 12UTC 1 November.

## STS BEBINCA (0021)

While Xangsane was located west of Luzon, Bebinca formed as a tropical depression north of Palau Island at 18UTC 30 October. It followed almost the same course that Xangsane took about six days before and developed into a tropical storm northeast of Mindanao Island at OOUTC 1 November. The storm further intensified into a severe tropical storm southeast of Luzon at 18UTC 1 November. It then started weakening around 18UTC 2 November, when it made landfall on the southern part of Luzon, and was downgraded into a tropical storm on the west coast of the Island at OOUTC 3 November. As Bebinca entered the South China Sea, it re-intensified to attain STS intensity again at 00UTC 4 November. It made a northward turn on 5 November and then a westward turn on 6 November with gradual weakening. The system weakened to a tropical depression southeast of Hong Kong at 00UTC 7 November.

## TS RUMBIA (0022)

A tropical depression formed west of Palau Island at 18UTC 27 November 2000. Moving west, it devel oped into a tropical storm over the same waters at 12UTC 28 November. Slightly turning to the west-northwest, Rumbia kept TS intensity until 18UTC 30 November, when it weakened into a tropical depression on southeastern Samar Island of the Philippines.

## TY SOULIK (0023)

Soulik was generated in late December and lived beyond the year-end for the first time in the last 15 years. A tropical depression formed east of Mindanao Island at 18UTC 28 December. It moved northward initially and then made westward turn toward the Philippines on the following day. On the westward track Soulik became a tropical storm about 200km east of Layte Island at 00UTC 30 December. The storm changed its track to the northeast and attained STS intensity at 18UTC 31 December. Soulik moved eastnortheastward keeping STS intensity until O0UTC 2 J anuary 2001, when it turned to the north-northeast south of Okinotorishima. After slightly weakening on the day, it moved northeastward and began to develop rapidly on 3 J anuary. The storm became a typhoon at 06UTC 3 J anuary and reached its peak with maximum sustained winds of 80 knots at 12UTC of the day. It however weakened quickly to a tropical depression over the same waters at 12UTC of the following day.

## Notes:

a. Underlined is fixed.
b. Abbreviations

| PSTN | $:$ | Position |
| :--- | :--- | :--- |
| MOVE | $:$ | Movement |
| PRES | $:$ | Pressure |
| MXWD | $:$ | Maximum wind |
| 24 HF | $:$ | 24-hour forecast |
| 48 HF | $:$ | 48-hour forecast |
| 72 HF | $:$ | 72-hour forecast |

c. Symbolic letters
i i : '20', '21', '22', '23', '24' or '25'.
YYGGgg : Time of observation submitting the data for analysis. Date(YY), hour(GG) and minute(gg) are given in UTC.
class : Intensity classification of the tropical cyclone. 'TY', 'STS', TS' or TD'.
ty-No. : Domestic identification number of the tropical cyclone adopted in J apan. Given in four digits and same as the international identification number.
name : Name assigned to the tropical cyclone from the name list prepared by the Typhoon Committee.
common-No. : International identification number of the tropical cyclones given in four digits.
LaLa.La : Latitude of the center position in "ANALYSIS" part.
LoLoLo.Lo : Longitude of the center position in "ANALYSIS" part.
confidence : Confidence of the center position. 'GOOD', 'FAIR' or 'POOR'.
direction : Direction of movement given in 16 azimuthal direction as ' N ', 'NNE', 'NE', 'ENE' etc.
SpSpSp : Speed of movement.
PPPP : Central pressure.
VmVmVm : Maximum sustained wind.
RdRdRd : Radii of 30knots and 50knots wind.
octant : Eccentric distribution of wind given in 8 azimuthal direction as 'NORTH', 'NORTHEAST', 'EAST' etc.

| YYGGgg $_{F}$ | $:$ | Time in UTC on which the forecast is valid. |
| :--- | :--- | :--- |
| LaLa.La $_{F}$ | $:$ | Latitude of the center of 70\% probability circle in "FORECAST" part. |
| LoLoLo.Lo $_{F}$ | $:$ | Longitude of the center of $70 \%$ probability circle in "FORECAST" part. |
| FrFrFr | $:$ | Radius of $70 \%$ probability circle. |

d. MOVE is optionally described as 'ALMOST STATIONARY' or '(direction) SLOWLY' depending on the speed of movement.

## User's Guide to the attached CD-ROM

Copyright (c) 2001 by the Japan Meteorological Agency (JMA) All Right Reserved.

1) This CD-ROM should not be reproduced and not be provided to any third party.
2) The source should be properly acknowledged in any work obtained with this CD-ROM.

JMA does not accept liability for any direct and/or indirect loss or damage to the user caused by the use of the software, data or documents in this CD-ROM.

## Preface

This CD-ROM contains all the texts, tables, charts in this report and GMS-5 satellite images of the tropical Cyclones that attained TS intensity or higher in the western North Padific and the South China Sea in 2000. This document is a brief user's guide for the CDROM. The CD-ROM was mastered in ISO-9660 format.

## Directory and File layout

|------ar405eng.exe (Acrobat Reader Installer)
|------Readme.txt (belief explanation about the CD-ROM)
|------Contents.pdf (contents of Annual Report 2000 in PDF)
|------TopMenu.exe (Start menu setup program)
|------Users_Manual.htm (user's manual of a satellite image viewer)
|------Annual_Report

|---2000_2 ( to 2000_23)
|------Users_Manual
|--Gmanual.doc (User's Manual for MS Word)
|------Andata
|--Best2000.txt (Best track data for the year 2000)

## How to use this CD-ROM

When you set the CD-ROOM, start menu will be presented automatically with a panel which has "Annual Report 2000", "GMS Satellite Images", "About CD-ROM" and "Close" buttons and a file list box for some introductory documents. Select and click a button or file which you want to see and follow instructions on your display.

Required hardware/OS for the CD-ROM are:
Hardware :DOS-V, NEC PC-9800 Series or their compatible
OS :Microsoft Windows Ver. 3.1 or later

## < Annual Report 2000 >

Annual Report 2000 is prepared in the following two formats: "PDF files" and "MS Word/Excel/PowerPoint files".

- PDF files:

Click the "Annual Report 2000" button to open the annual report 2000 in PDF. If you can not open the PDF file, install 'AdobeAcrobat Reader' with its installer (ar405eng.exe) in the file list box on a start menu window, and try again. 'Adobe Acrobat Reader' (or 'Adobe Acrobat') is required to view PDF files.

- Word/Excel/PowerPoint files:

Original texts, figures and tables prepared with Microsoft Word, Excel or PowerPoint are stored in Annual_Report holder of the CD-ROM.

## < GMS Satellite Images >

- Installation of a program for displaying satellite images:

Click the "GMS Satellite Image" button to run a setup program (Gsetup.exe) of a satellite image viewer. If you follow some instructions, the viewer 'Gmslpd.exe', which is a program for displaying satellite images, will be installed into the harddisk of your computer and a list of the tropical cyclones in 2000 is displayed in the 'Selection window' of satellite images for tropical cyclones.

- Displaying satellite images:

Select a tropical cyclone from the list and click the name, and 3-hourly satellite images for the tropical cyclone will be displayed. You can display the track of the tropical cyclone superimposed on the satellite image and measure the intensity of the tropical cyclone using Dvorak's technique.

- User's manual for the viewer:

Besides the above functions, the viewer has many useful ones. See the User's Manual (Users_Manual.htm or /Users_Manual/Gmanual.doc) about further detailed operations.

- Explanation of satellite image data

Period : From Generating Stage to Weakening Stage of each tropical cyclone.
Images : Infrared images (00, 03, 06, 09, 12, 15, 18, 21UTC) Visible images (00, 03, 06, 09, 21UTC)
Range : 40 degrees in both latitude and longitude. (The image window moves following a tropical cyclone's track so that the center of a tropical cyclone is fixed at the center of the image window.)
Time interval : 3-hourly
Resolution : 0.08 degrees in both latitude and longitude.
Compression of file : Compressed using 'compress.exe' command of Microsoft Windows.
< About CD-ROM >

Click the "About CD-ROM" button to open ReadmeE .txt file.
< Close >

Click the "Close" button to close start menu window.
< file list box >

You can open introductory document files from a file list box on the start menu window. Select a file and click the "Open" button or double click the file name.
